unit - II (Teaching ~~hrs~~ = 08)

Next

generation IP.

### Unit outcomes

- 2a. Map the given IPv4 address to IPv6 address.
- 2b. Describe function of the given step in the stateless auto configuration process.
- 2c. outline the given strategy of transition from IPv4 to IPv6
- 2d. Explain significance of the given field in datagram format of IPv6

TL

## 2.1 IP Addressing

- Representation → address space allocation
- Autoconfiguration
- Renumbering

## 2.2 Transition from IPv4 to IPv6

- Dual stack
- Tunneling
- Header translation

## 2.3 IPv6 protocol

- packet format
- Extension Header

## 2.1 IPV6 Addressing

- IPv6 designed to enable high performance and longer address space.
  - IPv6 was developed due to the address depletion of IPv4.

IPV6 address:

An IPv6 address is 128 bits long. It consists of 16 bytes.

1 2 3 4 5 6 7 8 9  
F0EE : ACG2 : 0001 : 000A : BBFF : 221A : 3087 : FFAF

## Notations :-

- Notations:-

  - An address is stored in the computer in the binary form (but it's impossible for humans to handle a 128-bit binary address). So, following notations are included:-

- (1) Dotted Decimal Notation:-
- This notation is rarely used for IPv6, it is used for IPv4 (only) for the compatibility with IPv4 address.
- This notation is superior for 4 byte IPv4 address but it is too long for 16 byte IPv6 address.
- e.g. 221.14.65.11.105.45.170.34.12.234.18.0.140

- (2) Colon Hexadecimal Notation.
- IPv6 address uses hexadecimal notation to make the address more readable.
- In this notation, 128 bits are divided into eight section, each 2 bytes in length.
- Two bytes in hexadecimal notation require four hexadecimal digit.
- 128 bit hexadecimal address contains 32 hex digits, with every digit is separated by a colon.

- (3) Mixed Representation
- Mixed representation of an IPv6 is the combination of dotted decimal and hexadecimal notation.
- this is required during the transition period in which IPv6 addresses that embed IPv4 addresses.

805B:2DGD:DC98:FC57:212:200:31:255

Binary	Decimal	Hexadecimal
0000	0	0
0001	1	1
0010	2	2
0011	3	3
0100	4	4
0101	5	5
0110	6	6
0111	7	7
1000	8	8
1001	9	9
1010	10	A
1011	11	B
1100	12	C
1101	13	D
1110	14	E
1111	15	F

#### (4) CIDR Notation:

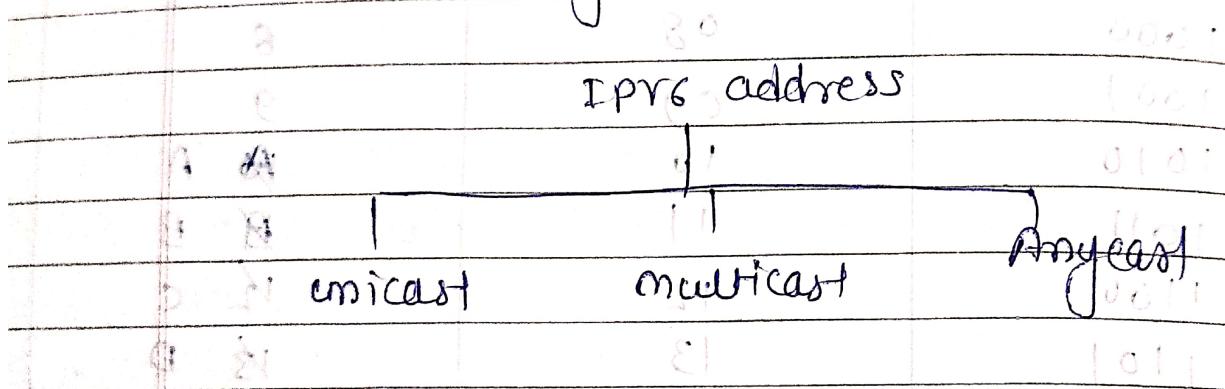

- IPv6 address are fundamentally divided into a number of network ID (8 bits) followed by a no. of host IP bits (80 bits) ~~160 bits~~
- IPv6 uses hierarchical addressing thus it requires CIDR (notation): 1000 101000 10010000
- The network identifier is called the prefix and the number of bits is used in splitting the prefix length. works similarly to mask on ~~as per~~ 805B: 2D9D: DC28: PC57: D4C8: FFFF/48.

## Address space

$$2^{128} = 34,000 \text{ trillion trillion trillion}$$

which is a very big number  
if we compare this with IPv4 then it can be seen that, the address space of IPv6 is 256 times bigger than that of IPv4

## Three Address types :-

### (1) unicast address:-

unicast Address identifies a single network interface. A packet sent to unicast address is delivered to the interface identified by that address

### (2) Anycast address:-

Anycast address is assigned to a group of interfaces. Any packet sent to anycast address will be delivered to only one member of interface (mostly nearest host possible)

- No special or separate address block is assigned for anycasting in IPv6.

## QUESTION & ANSWER

Multicast addresses:-

Multicast address is used by multiple hosts, called as Group, acquires a multicast destination address. These hosts need not be geographically together; if any packet is sent to this multicast address, it will be distributed to all interfaces corresponding to that multicast address.

QUESTION & ANSWER

1. 192.168.1.10	2. 192.168.1.10	3. 192.168.1.10
4. 192.168.1.11	5. 192.168.1.11	6. 192.168.1.11
7. 192.168.1.12	8. 192.168.1.12	9. 192.168.1.12
10. 192.168.1.13	11. 192.168.1.13	12. 192.168.1.13

QUESTION & ANSWER

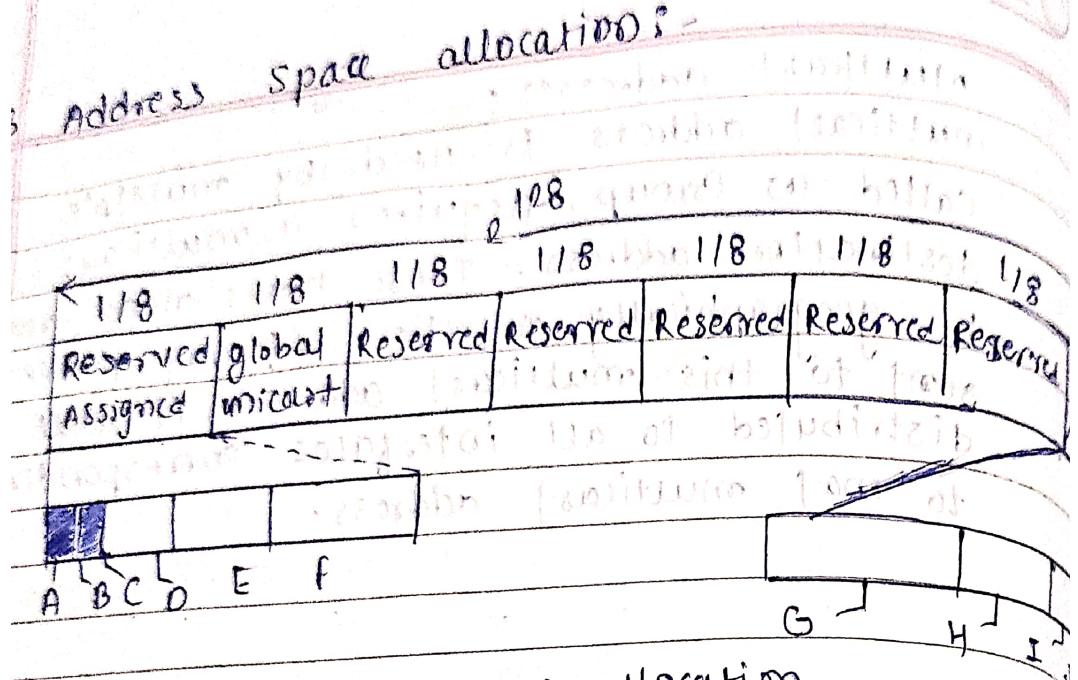

fig: Address space allocation.

A: IPv4 compatible	G: Reserved	M: Reserved
B: Reserved	H: Reserved	N: 1/256
C: Reserved	I: Reserved	multicast
D: Reserved	J: Unique local	
E: Reserved	K: Reserved	
F: Reserved	L: Link local	

IPv6 address space is divided into several blocks of varying size and each block is allocated for special purpose.

most of the block are still unassigned and have been left aside for future use  
IPv6 address space is divided into 8 equal ranges.

Each section is one-eighth of the whole address space

In IPv6 address space allocation

first and last section contains six and eight variable size blocks from which some of the blocks are reserved for

for special purposes, some are unassigned and some are used for unicast, multicast communication.

The leading bits in the address specify

the type of IPv6 address.

The variable-length field containing these

leading bits is called the **format prefix (FP)**.

- The allocation supports the direct allocation

of aggregate global unicast address, local

use address for multicast address, and interface

- Space is reserved for NSAPL, IPX interface address space is unassigned for future use.

- The remaining address space can be used for expansion of existing use.

- Anycast address are not shown here, bcz they are allocated out of the unicast address space.

• 32bit (64bit) IPv6 address is divided into

• 80bit (128bit) block as local

### 2.3.1 unicast Addresses:

IPv6 unicast consist of following forms:

1) **global unicast addresses** - same as public address in IPv4, public IP helps us to access the internet.

2) **link local address** - these addresses are auto-configured and we get information about this from neighbouring hosts. NDP protocol will work here.

3) **loopback** - IPv6 loopback represented in IPv6 as 1/28 bit form consisting of 128 bits.

4) **unspecified addresses** - when host doesn't know its own address, then unspecified address is used to send

- Date \_\_\_\_\_  
Page \_\_\_\_\_
- query to find unknown address of host
  - b) unique local : private address similar to IPv4
  - c) embedded address : two parts of embedded address (1) compatible (2) mapped, i.e. 7 bits of port number to 16 bits of address
  - d) additional address types can be defined in the future.
  - e) global unicast addresses are used for global communication they are similar in function to IPv4 address under CIDR.
  - f) classless (interdomain routing)
  - g) 48 bit represent the global unicast address.

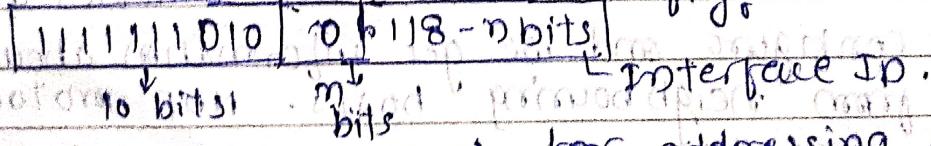

#### (A) local-use address (unique local address) :-

It is a unicast address that has only local routability scope. and can have a local or global uniqueness scope.

two types of local-use (unicast) address

- a) link-local :- describes link local if site-local :- use on a single site.

fig :- link-local

link local address used for addressing on a single link for purpose such as

auto-address configuration

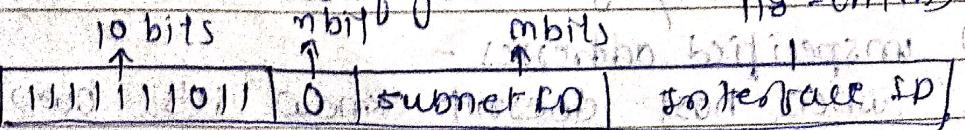

fig :- site-local-use address

for both type interface so must be unique

(B) unspecified Address;

- The unspecified address is a subblock which contains only one address all suffix bits to zero
  - During bootstrapping process, when a host does not know its own address, the unspecified address is used to send an enquiry to find the unknown address of the host.

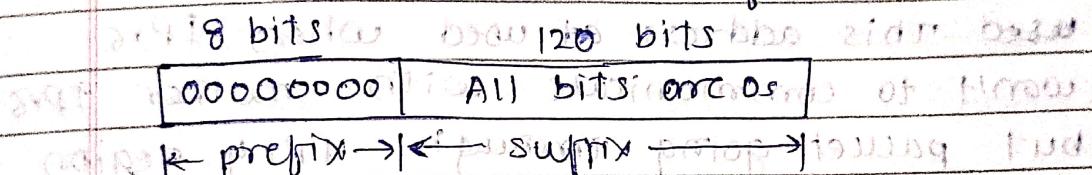

fig - format of the unspecified address.

## ④ Loopback address

Loopback address contains only one address which a host uses for testing itself without going into the net.

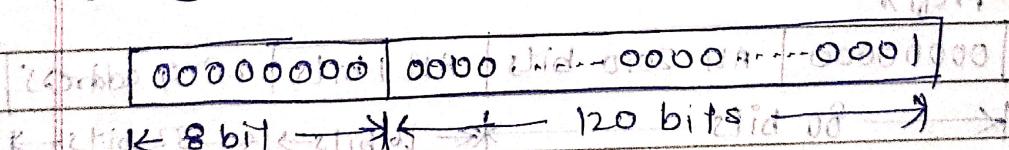

fig. format of the loopback address.

⑩ Embedded IPv4 address:

In migration from IPv4 to IPv6, in this transition period, the host can continue to use their IPv4 address which are embedded in IPv6 address.

- two formats are there

① compatible address is an IPRG address with 96 bits of zeros followed by 32 bits of IPR4 address.

0000 0000	All 0 bits	IPR4 address
-----------	------------	--------------

→ 96 bits → 32 bits → 32 bits

format of compatible address

- first bit is always 000000000000

used this address get used when IPRG want to communicate with another but packet going through IPR4 region or network.

(B) mapped ;

used when IPv6 computer wants to communicate with an IPv4 computer.

## prefix

The diagram illustrates the structure of an IP header. It shows the following fields and their bit widths:

- Version**: 4 bits
- IHL**: 4 bits
- DSCP**: 6 bits
- ECN**: 2 bits
- Total Length**: 16 bits
- Identification**: 16 bits
- Flags**: 3 bits
- Fragment Offset**: 13 bits
- TTL**: 8 bits
- Protocol**: 8 bits
- Source IP Address**: 32 bits
- Destination IP Address**: 32 bits

## Features of IPv6 - Winter 2019 2 marks

IPv6 is redesigned entirely such that it offers the following features:

a) Larger Address Space: IPv6 uses 128 bits address space which is 4 times more than the address space of IPv4.

- This address can accommodate almost everything under the sun.

b) Simplified Header

- All unnecessary information & options are moved to the end of IPv6 header, thus IPv6 header is more simplified.

IPv6 header is only twice as bigger than IPv4 provided the fact that IPv6 address is four times longer.

c) End-to-end Connectivity

- Every system now has unique IP address and traverse through the internet without using NAT or other translating components.

d) Auto-configuration:

IPv6 supports both stateful & stateless auto-configuration. If it's host device absence of a DHCP server does not put a halt on inter segment communication.

c) fast forwarding / routing  
1st part of the header puts all unnecessary information at the end of the header. The information contained in the first part is adequate for a router to take routing decisions.

d) IPsec: authentication and integrity  
Initially, it was decided that SFRS must have IPsec security, making it more secure than LPR4.

## 2.4 Auto configuration

- IPv4 hosts were configure manually  
later configuration protocol like DHCP enable servers to allocate IP automatically
- IPv6 has feature of auto-configure or self-configure we called it as stateless auto-configuration
- If DHCPv6 is there then we called it as stateful.

### stateless auto-configuration (SLAAC)

IPv6 has new features

- ① link-local address
- ② multicast
- ③ Neighbor Discovery (ND) protocol
- ④ generate Interface ID from Data link layer i.e. MAC.

IPv6 uses Router solicitation & advertisement message to learn IPv6 prefix, default router address from m/w router.

After obtaining prefix length and default router, IPv6 address from m/w routers, IPv6 m/w interface can automatically derive a global unicast IPv6 address using EUI-64 method.

### EUI-64 (Extended Unique Identifier)

↓ command

eg. `2001:0001:0002:0009::64 eui-64`

global 48 bit prefix

subnet

will take interface ID from data link layer

How it takes interface IP

e.g. suppose, mac address is

ABC; D903; 34E7 - 48 bit map

so, over here we need to add 16 bit FFFF because interface EP is 64 bit so we get 48 bit max from dentalink if 16 bit AEP we are going to add. (congig bit count add FFFF)

OABC : DGOB : B4E7

→ add FREE here

~~2001:0001:0002:0009:Dgff:FE03:34E7~~

pd-103-prior carbon 2192 transat 100% 0

The following is a summary of the steps (a device takes) when using stateless auto configuration.

pd-ims pd-ii 8000 ; 8000 ; 1000 ; 1000 1000

1981-AB-61 1981-AB-61 1981-AB-61 1981-AB-61 1981-AB-61 1981-AB-61

Urban Chor, at

三

### Step 1 :- Link-local Address generation:

- ① take 10 bits of link-local prefix 1111 1110 10
- ② add 54 zeros after 10 bits in total

typically this will be derived from the data link (MAC) hardware address.

### Step 2 :- Link-local Address uniqueness test

- It ensures uniqueness.

host then checks for uniqueness of local address. 64 bit interface identifier should be unique.

so host sends a neighbor solicitation message using Neighbor Discovery protocol (NDP).

It listens for neighbor advertisement

in response that indicates another device is already using it's link-local address.

If this happens then auto configuration is fail also. for that uniqueness is very important.

### Step 3 :- Link-local address assignment.

- If once uniqueness test is passed by using (NDP) then device assigns link-local address to its interface.

This generated address help to communicate locally we can't access internet using this address for that we need global unique address.

### Step 4 :- Router contact

node next attempts to contact local router for more information on continuing auto configuration.

this can be done by router solicitation & advertisement request.

Step 5: Router direction

- The router provides direction to the node on how to proceed with the auto configuration.
- It may tell the node either static config is going (DHCP)

alternately, it will tell the host how to determine its global internet address.

and go configuration and assign local IP

address to the host

Step 6: Global Address configuration

host will configure itself with its

globally unique Internet address.

this address formed from prefix/length

provided to the host by the router.

global address consisting part network ID

Renumbering of IP addresses

Renumbering of devices is a method

related to auto configuration, like host config

uration. It can be implemented using proto

col. (DHCP), through the life of IP address

(lease) "that expires after a period of

time". Local subnet specific network ID

under IPv6, network can be renumbered

by changing routers, especially on expiration

interval for network prefixes when a new

configuration is done (soft and cold)

they can send a new prefix to tell

devices to regenerate their IP address

devices can actually switch IP address

when they get information from their router

configuration and other

information about their network

information about their network

information about their network

## Transition from IPv4 to IPv6

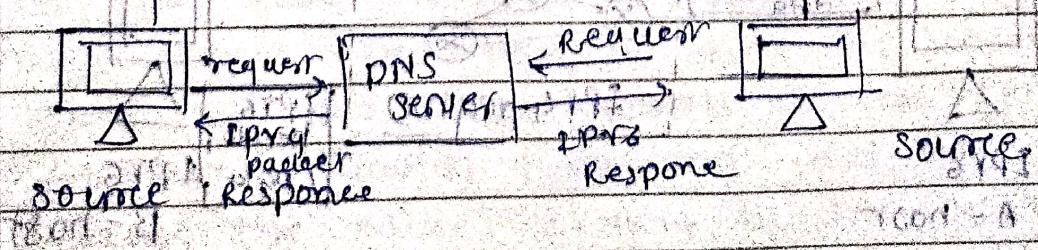

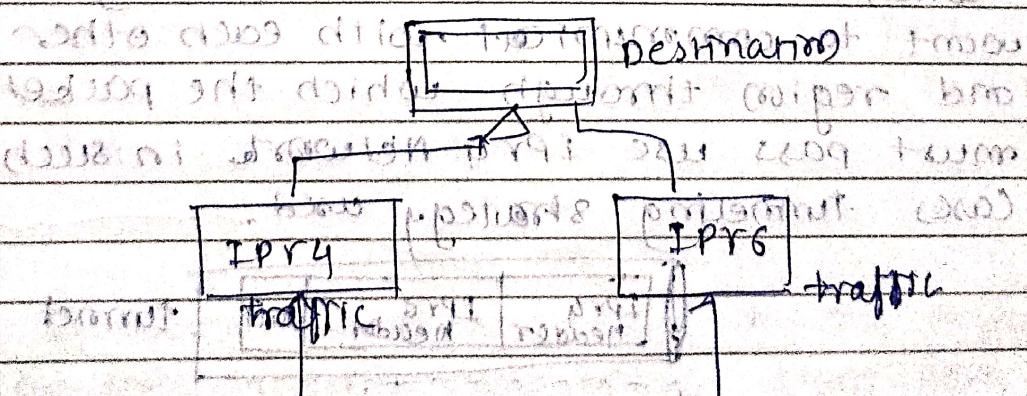

Evolution of transition (Quintero, 2019, - 4marks)

- When lower layer stops sending request from IPv4 address to an IPv6 address but it is not possible because IPv4 and IPv6 transition is not compatible.

- For solving this problem, we use some technologies.
- a) Dual stack Router,
  - b) Tunneling
  - c) Header translation

### a) Dual stack Router :-

In dual stack router, a router interface is attached with both IPv4 & IPv6, it can

e.g. Microsoft Edge

- Before completely migrating to version 6 it is recommended that all hosts should have a dual stack of protocol at the time of transition. i.e., both the simultaneously station should run IPRv4 & IPRv6 at the same time.
- A source host sends query to the DNS for deciding which version of IP to use while sending a packet to a destination

- A source host sends IPRv4 packet, if a an IPRv4 address is returned by other DNS and send IPRv6 packet if DNS returns IPRv6 address

## 2) Tunneling :-

when two computers are residing in different regions through which the packet must pass use IPRv6 Network in such cases tunneling strategy used.

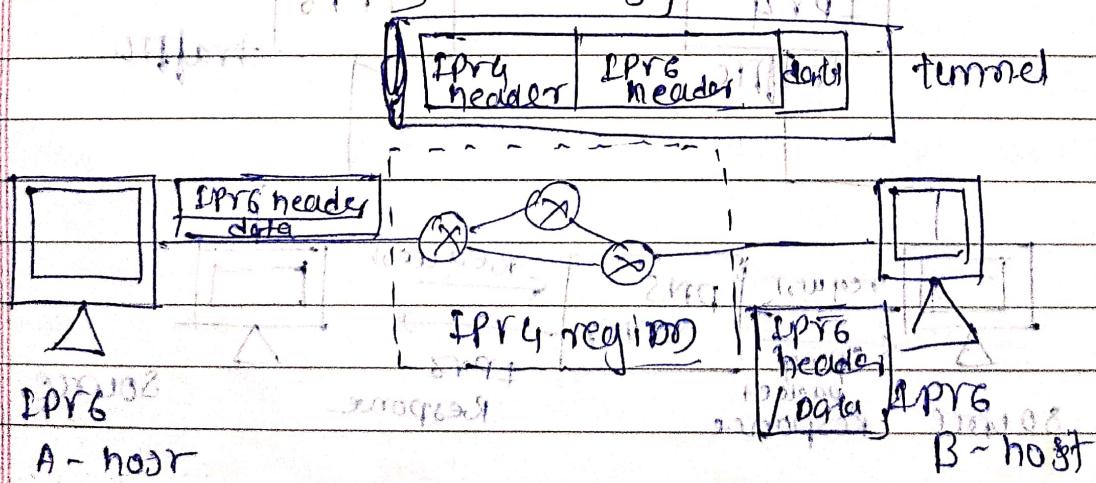

Fig. 13. Tunneling

- when a packet enters in IPv4 region it encapsulate in IPv6 packet & when it exit the region it leaves the packet again
- It looks like IPv6 packet enters in tunnel from one end. encoded with IPv4 & come out from tunnel as IPv6.
  - The protocol value set to 41 for holding IPv6 packets by IPv4 packet.
  - tunneling protocol PGP point to point protocol

### 8.) Header translation :-

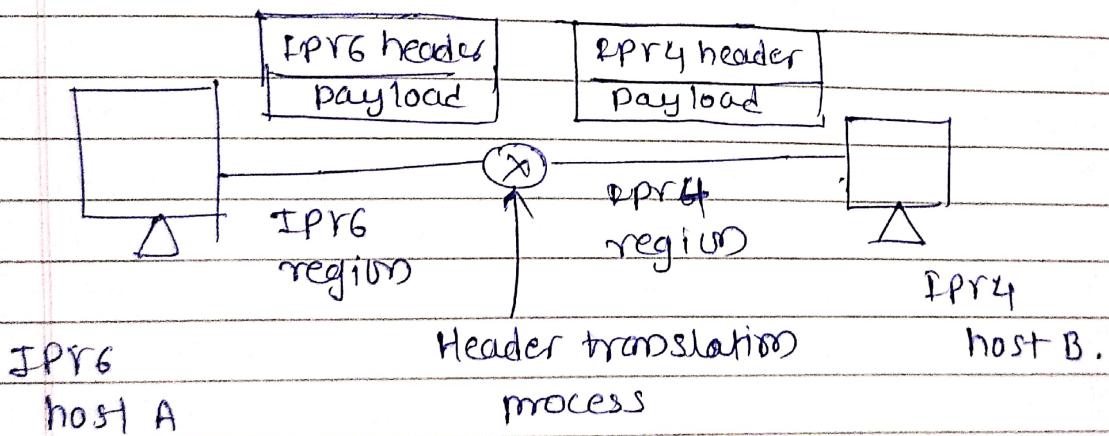

Fig - Header translation.

- If some systems use IPv4 & the majority of the internet has moved from IPv4 to IPv6 in that case header translation strategy is used where the receiver does not understand IPv6 but the sender wants to use IPv6 only.
- In this situation tunneling will not work because the packet should be in the IPv4 format which has to be understood by the receiver.

In this strategy through headers translation the format of header must be totally changed. As per the convert the header type. The  $\text{IPR}_6$  packet header is converted into an  $\text{IPR}_4$  header. In this case the  $\text{IPR}_6$  header is converted into  $\text{IPR}_4$  header. The  $\text{IPR}_6$  header has 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number. The  $\text{IPR}_4$  header has 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

### Conversion of $\text{IPR}_6$ header into $\text{IPR}_4$ header

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

The conversion of  $\text{IPR}_6$  header into  $\text{IPR}_4$  header is done by removing the 16 bits of header length, 16 bits of total length, 16 bits of identification, 8 bits of flags and 16 bits of sequence number.

## Difference between IPv4 and IPv6 (W-19)

2 - marks.

### IPv4

### IPv6

1) IPv4 has 32-bit address length

IPv6 has 128-bit address length

2) IPv4 has  $2^{32}$  bits address space.

IPv6 has  $2^{128}$  bits address space

3) IPv4 address written in dotted decimal notation.

IPv6 address written in hexadecimal & consists of 8 groups containing 4 hex digit.

4) Length of IPv4 header is minimum 20 byte to 60 byte maximum and it uses 13 fields to identify various control setting

It is static header of 40 bytes in length and has only 8 fields. Option information is carried by extension header.

5) It supports manual and DHCP address configuration.

It supports Auto & renumbering address configuration.

6) In IPv4 end to end connection integrity is unachievable

In IPv6 end to end connection integrity is achievable

7) source and destination address are of 32 bits

source & destination address are of 128 bit

6) security features is dependent on app<sup>d</sup> thus IPsec support is optional.

IPSEC is inbuilt security feature in the IPRG protocol.

7) fragmentation performed by sender & forwarding routers

In IPRG fragmentation performed only by sender.

8) In IPRG encryption and authentication facility not provided

In IPRG encryption and authentication are not provided.

9) standard header of IP is added at end of each frame & removed at receiving end. standard header is added once per packet.

10) original sequence number is maintained throughout the connection.

11) loss of link will not affect sequence number.

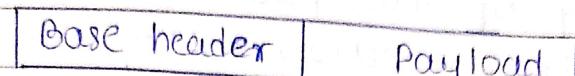

12) sequence number is not required.

## IPV6 protocol Packet format

classmate

Date \_\_\_\_\_  
Page \_\_\_\_\_

→ 40 byte → ← 65,535 bytes

fig : IPV6 packet

- Base header is mandatory part and payload is optional one.

The payload is made up of two parts

1. An optional extension header
2. The upper layer data.

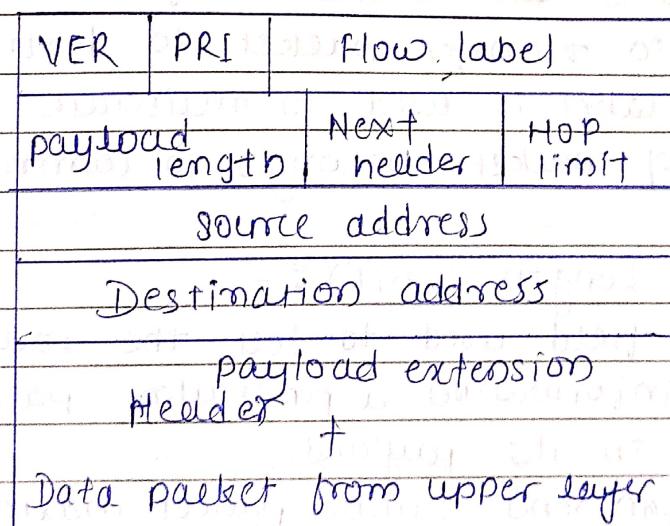

fig : Format of IPV6 Datagram.

base header (Base header)

(4 bit)

VER (version) : The contents of 4 bit field defines the version of IP such as IPV4 or IPV6. If VER = 6, then the version is IPV6 i.e 10110.

Priority (4 bit) This 4 bit field contains defines the priority of the packet which is important in connection with the traffic congestion. If the packet comes in new then according to priority we forward pass 4 low priority packet discard.

Flow label (24) It is a 24 bit (3 bytes)

It designed for real-time data processing means no delay in data transfer with minimal loss.

- so datagram service convert in to virtual circuit.
- virtual circuit decide to follow only one path to transfer packet to destination
- flow label is used to maintain the sequence of packets belonging to communication

Payload Length (16 bit) :-

This field used to tell the router how much information a particular packet contains in its payload.

You can send jumbo packet maximum 4GB data for this we need extension header.

If the extension header contains Hop by hop extension header then payload may exceed

Next Header (8 bit)

Base Header	extension Header	...	Extension header	payload
				40 byte

This field is used to tell the router how much information a potential packet contain in its payload.

This field is used to indicate either the type of extension header, or if the extension header is not present then it indicate the upper layer.

### Hop Limit (8 bit)

This field is used to indicate either the type of extension header

This field is used to stop packet to loop in the network infinitely. This is same as TTL in IPv4. The value of Hop limit field is decremented by 1 as it passes a link when field reaches 0 the packet discard.

Source Address (128 bit): indicate the address of originator of packet.

Destination Address (128 bit): indicate the destination address.

Used to establish connection.

Used to identify the host to which destination address belongs.

~9.03 QM 14/14/94

Successor address of node 1234567890.

## Extension Header

- IPv6 fixed header keeps only necessary information for routers, all other information that is not necessary and rarely used not included in fixed header.
- such information but no extension header, when extension header are used, IPv6 fixed Next-header field points to the second one and so on.
- If Next header contain the value 59, it indicate that there are no header after this header, not even upper layer header.

The sequence of extension Header should be

- 1) IPv6 Header
- 2) Hop by Hop options header
- 3) Destination options header
- 4) Routing header
- 5) Fragment header
- 6) Authentication header
- 7) encapsulating security payload
- 8) Destination options header 2

Routing Headers :- (Ch 3)

contains methods to support making routing decision means you can decide the route of packet travel from source to destination. sender decides the path of packet.

Hop by Hop (0) :-

at each particular hop we provide information

## Fragmentation Header (44)

IPv6 intermediate routers can't fragment only source can. If fragment offset value is given in next header, then indicate; fragmentation is done.

## Authentication Headers - (51)

Provide authentication service, password for data integrity maintaining the data from

## Destination options (60)

Data only read by destination node

## Encryption security (50)

Encryption information.

## important questions of unit 2

- Q.1) features of IPv4 describe?
- Q.2) difference b/w IPv4 and IPv6?
- Q.3) what is autoconfiguration in IPv6?
- Q.4) explain unicast addresses?
- Q.5) explain different transition method of IPv4 & IPv6
- Q.6) explain IPv6 extension header
- Q.7) Draw and explain IPv6 packet format with neat diagram.
